Abstract

Seasonal Variability of Heavy metal in Fish species organs in Upper River in Yola Adamawa State was investigated from May 2018 to April 2019. Fish species of commercial importance (*Auchenoglanis occidentalis*, *Oreochromis niloticus* and *Clarias gariepinus*) were sampled monthly in triplicate for the twelve months. The entire fish samples (*Auchenoglanis occidentalis*, *Oreochromis niloticus* and *Clarias gariepinus*) were separated and scales were removed (for those with scales) and washed with running water before dissecting with sterile scissors to remove gills, livers and muscles. Wet digestion technique was used as described by AOAC (2002). Seasonal variability of Heavy metals in fish species Organs were determined by comparing levels obtained in Wet season with the level obtained in Dry season. Data obtained in this study were subjected to descriptive statistics to establish means, standard errors. One way analysis of variance (ANOVA) was used to determine the mean significant seasonal variation (at 0.05) of heavy metals in the fishes from the sampling stations using Statistical Package for Scientists and Engineers (Statistix 9.0). All the heavy metals investigated were present in fish organs except cadmium and chromium which were also below detection level. The mean values of heavy metals obtained in this study revealed that, metals accumulate more in the organs of fish species in dry season than in the wet season. The trend of the accumulation of metal in the study was Zn>Cu>Pb>Ni. The trend of the accumulation of metal in the organs of fish species in this study was liver>liver>flesh>liver of *C.gariepinue*>*C.gariepinue*>*O.niloticus*> *C.gariepinue* Heavy metals Cu, Ni, Pb and Zn recorded their highest values (1.27±0.18mg/kg, 0.31±0.13mg/kg, 0.94±0.05mg/kg and 1.64±0.14mg/kg) in dry season (April, March, December and January) respectively, when compared with wet season in fish of Upper River Benue

Keywords: Heavy metal, Upper Benue, *Auchenoglanis occidentalis*, *Oreochromis niloticus* and *Clarias gariepinus*

Introduction

Heavy metals belong to the group of elements whose hydro-geochemistry cycles have been greatly accelerated by man. The rapid industrialization, coupled with technological advances in agriculture, has introduced various pollutants (synthetic and organic) into the aquatic ecosystems, which serves as the ultimate sink for most metals (Ogbeibu and Ezeunara, 2002). Fish accumulate toxic chemicals such as heavy metals directly from water and diet, and contaminant residues may ultimately reach concentrations hundreds or thousands of times above those measured in the water, sediment and food (Osman *et al.*, 2007). Adeyeye *et al.* (1996) reported that the concentration of metals is a function of fish species as it accumulates more in some fish species

than others. Most heavy metals have no beneficial functions to the body and can be highly toxic. If they enter into the body through inhalation, ingestion and skin they accumulate in the body tissue faster than the body's detoxification pathways can dispose of them (Ekpo *et al.*, 2008). High concentration exposure is not necessary to produce a state of toxicity in the body tissue and, overtime, can reach toxic concentration at low levels (Prusty, 1994). Heavy metal toxicity can result in damaged or reduced mental and central nervous function, lower energy levels, and damage to blood composition, lungs, kidneys, liver, and other vital organs of the fish (Edward *et al.* 2016). Long-term exposure may result in slowly progressing physical, muscular, and neurological degenerative processes. The

bioaccumulation of heavy metals in living organisms and biomagnifications describes the processes and pathways of pollutants from one trophic level to another. Various species of fish are mostly used as bio-indicators of heavy metals contamination (Svobodovo *et al.*, 2004).

Upper Benue River receives a wide variety of waste from almost every significant human activity. These include mostly the dumping of domestic wastes, sewage and agricultural wastes. The wastes dumped on land are washed into the river through surface run off. Agricultural activity like farming in both wet and dry season also takes place in this area. Fertilizers, Pesticides and herbicides are extensively used in agricultural production to increase yield and also to control pests, diseases, weeds and other plant pathogens in an effort to reduce or eliminate yield losses and preserve high quality product. These wastes generated flows into the river and may contaminate the water with a variety of contaminants especially heavy metals. Such contaminations might accumulate in various organs of fishes; and such accumulation may affect humans and other species that depend on such fish as food. The presence of heavy metals in aquatic animals like fish is becoming a threat, thereby making them unfit for human consumption. In order to effectively control and manage these, it is imperative to have a clear variability of heavy metal concentration in fishes from Upper Benue River; hence the need for this research.

Materials and Methods

Study Area

Adamawa State is located at the North Eastern part of Nigeria. It lies between latitude 7° and 11° N of the equator and between longitude 11° and 14° E of the Greenwich meridian.

Duration of Sampling

The study was conducted for the period of twelve months (12). May 2018 to April 2019. The months of May to October constituted the wet season while the months of November to April constituted the dry season (Adebayo and Tukur 1999, UBRDA, 1985). Fish samples were collected monthly in triplicate for the twelve months.

Fish Sampling Protocol

Fish species of commercial importance (*Auchenoglanis occidentalis*, *Oreochromis niloticus* and *Clarias gariepinus*) were bought from fish mongers at the study sites. A random composite sampling technique was used without discrepancies for sexes in species. Fish sample was collected in triplicate. The fish samples were transported to the laboratory for Identification, measurement and dissection.

Fish Samples Digestion

The entire fish samples (*Auchenoglanis occidentalis*, *Oreochromis niloticus* and *Clarias gariepinus*) were separated. Scales were removed (for those with scales) and washed with running water before dissecting with sterile scissors to remove gills, livers and muscles. Wet digestion technique was used as described by AOAC (2002). The procedure of wet digestion was carried out by transferring 5.0g of gills, liver and muscles of the fish species into Kjeldahl flask each and 25ml digestion acid (60% Perchloric acid and 71% nitric acid in the ratio 1:4) was added. The mixture were swirled and heated gently at first until frothing stopped. Thereafter the mixtures were heated until a clear light green solution was obtained. This was allowed to cool and filtered into a 100ml volumetric flask. All the digested liquors were filtered through Whatman 541 filter paper. Distilled water was then added to make up to the mark and ready for metal analysis.

Determination of Heavy Metal in Fish Species

Determination of Heavy metal like Cu, Cd, Cr, Ni, Pb and Zn were made directly on each final solution using a Buck Scientific 200A model, Atomic Absorption Spectrophotometer (AAS) and the values obtained were expressed in milligram per kilogram (kg). Procedural blanks were prepared and aspirated along with the analytical samples in order to correct for background absorption. The levels of heavy metals in muscles, gills and liver were evaluated by comparing the statistical mean levels of the metals in the flesh, gills and liver samples.

Data Analysis

Data obtained in this study were subjected to descriptive statistics to establish means, standard errors, one way analysis of variance (ANOVA) was used to determine the mean significant seasonal variation (at 0.05) of heavy metals in the fishes from the sampling stations using Statistical Package for Scientists and Engineers (Statistix 9.0).

Results

Heavy metal present in the different organs of the different fish species is presented on Tables 1-4. All the heavy metals investigated were present in fish organs except cadmium and chromium which were below detection level.

Table 1 shows the mean standard error and range of Copper present in the organs of *A. occidentalis*, *O. niloticus* and *C. gariepinus*. Copper recorded its highest value of 1.28 ± 0.18 mg/kg in the liver of *C. gariepinus* in April (dry season) while the lowest value 0.34 ± 0.17 mg/kg was recorded in the gills of *O. niloticus* in July (Wet season). There was significant difference in variability between season and fish species ($P < 0.05$).

Table 2 shows the mean standard error and range of Nickel (Ni) present in the organs of *A. occidentalis*, *O. niloticus* and *C. gariepinus*. The highest Nickel (Ni) value of 0.31 ± 0.18 mg/kg was recorded in the flesh of *C. gariepinus* in the month of March (dry season) while the lowest value 0.03 ± 0.04 mg/kg was recorded in the liver of *O. niloticus* in July (Wet season). There was significant difference in variability between season and fish species ($P < 0.05$).

Table 3 shows the mean standard error and range of Lead (Pb) present in the organs of *A. occidentalis*, *O. niloticus* and *C. gariepinus*. Lead (Pb) recorded its highest value of 0.94 ± 0.05 mg/kg in the liver of *O. niloticus* in December (dry season) while the lowest value 0.01 ± 0.12 was recorded in the gills of *A. occidentalis*, gills and flesh of *C. gariepinus* in July, June (Wet season). There was significant difference in variability between season and fish species ($P < 0.05$).

Table 4 shows the mean standard error and range of Zinc (Zn) present in the organs of *A. occidentalis*, *O. niloticus* and *C. gariepinus*. The highest Zinc (Zn) value of 1.64 ± 0.14 mg/kg was recorded in the liver of

C. gariepinus in the month of January (dry season) while the lowest Zinc (Zn) value 0.21 ± 0.13 was recorded in the gills and flesh of *A. occidentalis*, and flesh of *C. gariepinus* in the month of July, June (Wet season). There was significant difference in variability between season and fish species ($P < 0.05$).

Discussion

The result of this study showed a significant variability in the accumulation of heavy metals in the different organs of fish species. The mean values of heavy metals obtained in this study revealed that, metals accumulate more in the organs of fish species in dry season than in the wet season (Edward *et al* 2016). The trend of the accumulation of metal in the study was Zn>Cu>Pb>Ni. The trend of the accumulation of metal in the organs of fish species in this study was liver>liver>flesh>liver of *C.gariepinue* > *C.gariepinue*>*O. niloticus*> *C.gariepinue*. The variation in metal concentration in the fish organs was due to different sources of metal pollution, intensive human activities and discharge of municipal waste. Generally, heavy metal concentrations in the tissue of freshwater fish vary considerably among different studies (Chattopadhyay *et al.*, 2002, Papagiannis *et al.*, 2004), possibly due to differences in metal concentrations and chemical characteristics of water from which fish were sampled, ecological needs, metabolism and feeding patterns of fish and also the season in which studies were carried out. In the present study, cadmium and chromium were below detection level in fish organs. This is true according to the report of some researchers who reported that, multiple factors including season, physical and chemical properties of water can play a significant role in metal accumulation in different fish organs (Hayat *et al.*, 2007). Obasohan and Eguavoen (2008) also stated that dry season affects the accumulation of heavy metals in water, sediments and its reared fish. All the mean values obtained in wet and dry seasons in this study were within the allowable limits for fish food except lead.

Conclusion

The values obtained in this study revealed that, metals accumulate more in the tissues of fish organs in dry season than in the wet season. Generally, the dry season recorded higher heavy metals than the wet season. The values obtained in this study revealed that, metals accumulate more in the tissues of fish organs in dry season than in the wet season. Generally, the dry season recorded higher heavy metals than the wet season. From the above findings therefore, Upper Benue River fish species investigated are said to be moderately polluted with

these heavy metals especially in the dry season. Lead is the common heavy metal in fish which was present and above recommended permissible limits.
